

SAOOA

Surrogate Assisted Online Optimization
Algorithm

Radek Bartyzal
rbartyzal1@gmail.com

Problems

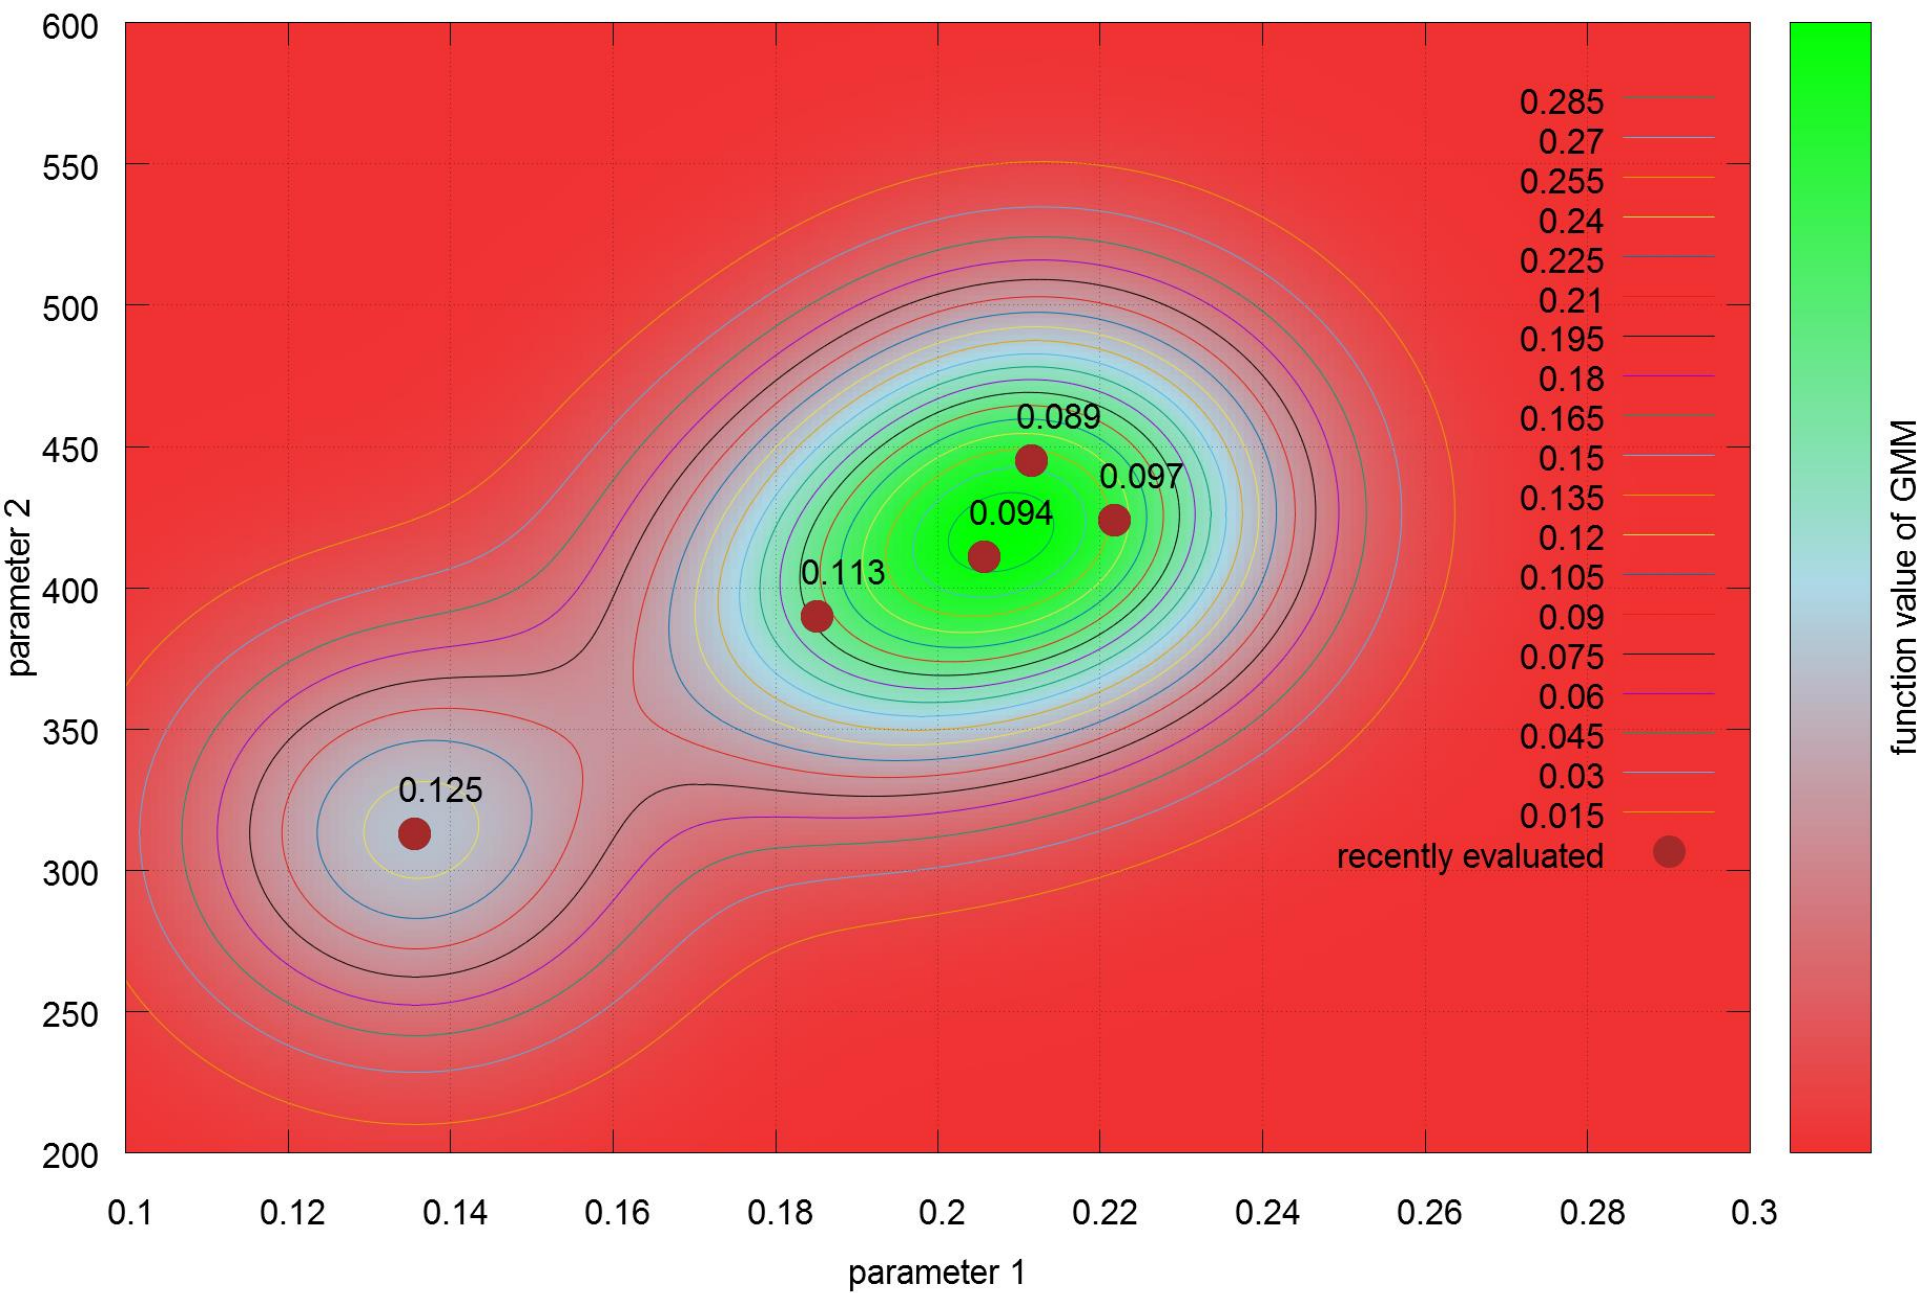

- Very expensive evaluation
- Dynamic environment
- Noise
- Evaluation of bad individuals should be avoided

Solution

- Online optimization
- Gaussian Mixture Model = GMM
- Penalization of sub-average gaussians
- Simulated annealing
- Elitist selection
- Detection of and reaction to sudden changes

Algorithm description

- param configuration = point = individual
1. Evaluate initial individual
 2. Create GMM based on current population
 3. Generate new individuals according to the GMM
 4. Remove individuals older than 3 generations from population

Problems

- Expensive eval = kind of solved by GMM
(there is no real solution)
- We don't want to evaluate bad individuals
=> need of convergence
=> **simulated annealing**

Get from this:

To this:

Problems

- Noisy measurements could catapult us far away
 - => we need to be more conservative
 - => **elitist selection**
 - => stabilizes exploration
 - => allows tracking of changes in the environment

Problems

- A sudden change in the environment usually implies a change of the fitness landscape
 - => we need to start exploring more
 - = increased exploration rate
 - = increased standard deviation of gaussians

Solution revisited

- Gaussian Mixture Model = GMM
- Penalization of sub-average gaussians
- Simulated annealing
- Elitist selection
- Detection of and reaction to sudden changes
